

# CS 33

## Libraries

# Libraries

- Collections of useful stuff
- Allow you to:
  - incorporate items into your program
  - substitute new stuff for existing items
- Often ugly ...

## Creating a Library

```
$ gcc -c sub1.c sub2.c sub3.c
$ ls
sub1.c      sub2.c      sub3.c
sub1.o      sub2.o      sub3.o
$ ar cr libpriv1.a sub1.o sub2.o sub3.o
$ ar t libpriv1.a
sub1.o
sub2.o
sub3.o
$
```

Files ending with “.a” are known as *archives* or *static libraries*.

## Using a Library

```
$ cat prog.c
int main() {
    sub1();
    sub2();
    sub3();
}
$ cat sub1.c
void sub1() {
    puts("sub1");
}
```

```
· $ gcc -o prog prog.c -L. -lpriv1
· $ ./prog
· sub1
· sub2
· sub3
·
```

Where does *puts* come from?

```
$ gcc -o prog prog.c -L. \
-lpriv1 \
-L/lib/x86_64-linux-gnu -lc
```

The routine “puts” is from the standard-I/O library, just as printf is, but it’s far simpler. It prints its single string argument, appending a ‘\n’ (newline) to the end.

Note that “-lpriv1” (the second character of the string is a lower-case L and the last character is the numeral one) is, in this example, shorthand for libpriv1.a, but we’ll soon see that it’s shorthand for more than that.

Normally, libraries are expected to be found in the current directory. The “-L” flag is used to specify additional directories in which to look for libraries.

# Static-Linking: What's in the Executable

- **ld puts in the executable:**
  - » (assuming all .c files have been compiled into .o files)
  - all .o files from argument list (including those newly compiled)
  - .o files from archives as needed to satisfy unresolved references
    - » some may have their own unresolved references that may need to be resolved from additional .o files from archives
    - » each archive processed just once (as ordered in argument list)
      - order matters!

## Example

```
$ cat prog2.c
int main() {
    void func1();
    func1();
    return 0;
}
$ cat func1.c
void func1() {
    void func2();
    func2();
}
$ cat func2.c
void func2() {
}
```

## Order Matters ...

```
$ ar t libf1.a  
func1.o  
$ ar t libf2.a  
func2.o  
$ gcc -o prog2 prog2.c -L. -lf1 -lf2  
$  
$ gcc -o prog2 prog2.c -L. -lf2 -lf1  
./libf1.a(sub1.o): In function `func1':  
func1.c:(.text+0xa): undefined reference to `func2'  
collect2: error: ld returned 1 exit status
```

## Substitution

```
$ cat myputs.c
int puts(char *s) {
    write(1, "My puts: ", 9);
    write(1, s, strlen(s));
    write(1, "\n", 1);
    return 1;
}
$ gcc -c myputs.c
$ ar cr libmyputs.a myputs.o
$ gcc -o prog prog.c -L. -lpriv1 -lmyputs
$ ./prog
My puts: sub1
My puts: sub2
My puts: sub3
```

## An Urgent Problem

- **printf is found to have a bug**
  - perhaps a security problem
- **All existing instances must be replaced**
  - there are zillions of instances ...
- **Do we have to re-link all programs that use printf?**

# Dynamic Linking

- **Executable is not fully linked**
  - contains list of needed libraries
- **Linkages set up when executable is run**

# Benefits

- **Without dynamic linking**
  - every executable contains copy of printf (and other stuff)
    - » waste of disk space
    - » waste of primary memory
- **With dynamic linking**
  - just one copy of printf
    - » shared by all

# Shared Objects: Unix's Dynamic Linking

## 1 Compile program

## 2 Track down references with *ld*

- *archives* (containing *relocatable objects*) in “.a” files are statically linked
- *shared objects* in “.so” files are dynamically linked
  - » names of needed .so files included with executable

## 3 Run program

- *ld-linux.so* is invoked first to complete the linking and relocation steps, if necessary

Linux supports two kinds of libraries — static libraries, contained in *archives*, whose names end with “.a” (e.g. *libc.a*) and *shared* objects, whose names end with “.so” (e.g. *libc.so*). When *ld* is invoked to handle the linking of object code, it is normally given a list of libraries in which to find unresolved references. If it resolves a reference within a .a file, it copies the code from the file and statically links it into the object code. However, if it resolves the reference within a .so file, it records the name of the shared object (not the complete path, just the final component) and postpones actual linking until the program is executed.

If the program is fully bound and relocated, then it is ready for direct execution. However, if it is not fully bound and relocated, then *ld* arranges things so that when the program is executed, rather than starting with the program's main routine, a runtime version of *ld*, called *ld-linux.so*, is called first. *ld-linux.so* maps all the required libraries into the address space and then calls the main routine.

## Creating a Shared Library (1)

```
$ gcc -fPIC -c myputs.c
$ ld -shared -o libmyputs.so myputs.o
$ gcc -o prog prog.c -L. -lpriv1 -lmyputs
$ ./prog
./prog: error while loading shared libraries: libmyputs.so:
cannot open shared object file: No such file or directory
$ ldd prog
linux-vdso.so.1 => (0x00007fff953fc000)
libmyputs.so => not found
libc.so.6 => /lib/x86_64-linux-gnu/libc.so.6 (0x00007f7389174000)
/lib64/ld-linux-x86-64.so.2 (0x00007f7389536000)
```

The `-fPIC` flag tells `gcc` to produce “position-independent code,” which is something we discuss soon. The `ld` command invokes the loader directly. The `-shared` flag tells it to create a shared object. In this case, it’s creating it from the object file `myputs.o` and calling the shared object `libmyputs.so`.

The error occurs because we haven’t indicated in the executable (`prog`) where `ld-linux.so` should look for shared objects. The `ldd` (list dynamic dependencies) command, which looks at all the shared objects referenced in the executable and prints out where they are found, shows us what the problem is.

## Creating a Shared Library (2)

```
$ gcc -o prog prog.c -L. -lpriv1 -lmyputs -Wl,-rpath \
/home/twd/libs
$ ldd prog
linux-vdso.so.1 => (0x00007fff235ff000)
libmyputs.so => /home/twd/libs/libmyputs.so (0x00007f821370f000)
libc.so.6 => /lib/x86_64-linux-gnu/libc.so.6 (0x00007f821314e000)
/lib64/ld-linux-x86-64.so.2 (0x00007f8213912000)
$ ./prog
My puts: sub1
My puts: sub2
My puts: sub3
```

The “-Wl,-rpath /home/twd/libs” flag (the third character of the string is a lower-case L) tells the loader to indicate in the executable (prog) that ld-linux.so should look in the indicated directory for shared objects. (The “-Wl” part of the flag tells gcc to pass the rest of the flag to the loader.)

## Order Still Matters

- All shared objects listed in the executable are loaded into the address space
  - whether needed or not
- `ld-linux.so` will find anything that's there
  - looks in the order in which shared objects are listed

## Versioning

```
$ gcc -fPIC -c myputs.c
$ ld -shared -soname libmyputs.so.1 \
-o libmyputs.so.1 myputs.o
$ ln -s libmyputs.so.1 libmyputs.so
$ gcc -o prog1 prog1.c -L. -lpriv1 -lmyputs \
-Wl,-rpath .
$ vi myputs.c
$ gcc -fPIC -c myputs.c
$ ld -shared -soname libmyputs.so.2 \
-o libmyputs.so.2 myputs.o
$ rm -f libmyputs.so
$ ln -s libmyputs.so.2 libmyputs.so
$ gcc -o prog2 prog2.c -L. -lpriv1 -lmyputs \
-Wl,-rpath .
```

Here we are creating two versions of `libmyputs`, in `libmyputs.so.1` and in `libmyputs.so.2`. Each is created by invoking the loader directly via the “`ld`” command. The “`-soname`” flag tells the loader to include in the shared object its name, which is the string following the flag (“`libmyputs.so.1`” in the first call to `ld`). The effect of the “`ln -s`” command is to create a new name (its last argument) in the file system that refers to the same file as that referred to by `ln`’s next-to-last argument. Thus, after the first call to `ln -s`, `libmyputs.so` refers to the same file as does `libmyputs.so.1`. Thus the second invocation of `gcc`, where it refers to `-lmyputs` (which expands to `libmyputs.so`), is actually referring to `libmyputs.so.1`.

Then we create a new version of `myputs` and from it a new shared object called `libmyputs.so.2` (i.e., version 2). The call to “`rm`” removes the name `libmyputs.so` (but not the file it refers to, which is still referred to by `libmyputs.so.1`). Then `ln` is called again to make `libmyputs.so` now refer to the same file as does `libmyputs.so.2`. Thus when `prog2` is linked, the reference to `-lmyputs` expands to `libmyputs.so`, which now refers to the same file as does `libmyputs.so.2`.

If `prog1` is now run, it refers to `libmyputs.so.1`, so it gets the old version (version 1), but if `prog2` is run, it refers to `libmyputs.so.2`, so it gets the new version (version 2). Thus programs using both versions of `myputs` can coexist.

# Interpositioning

## How To ...

```
int __wrap_puts(const char *s) {  
    int __real_puts(const char *);  
  
    write(2, "calling myputs: ", 16);  
    return __real_puts(s);  
}
```

*\_\_wrap\_puts* is the “wrapper” for *puts*. *\_\_real\_puts* is the “real” *puts* routine. What we want is for calls to *puts* to go to *\_\_wrap\_puts*, and calls to *\_\_real\_puts* to go to the real *puts* routine (in *stdio*).

## Compiling/Linking It

```
$ cat tputs.c
int main() {
    puts("This is a boring message.");
    return 0;
}
$ gcc -o tputs -Wl,--wrap=puts tputs.c myputs.c
$ ./tputs
calling myputs: This is a boring message.
$
```

The arguments to gcc shown in the slide cause what we asked for in the previous slide to actually happen. Calls to *puts* go to *\_\_wrap\_puts*, and calls to *\_\_real\_puts* go to the real *puts* routine.

## How To (Alternative Approach) ...

```
#include <dlfcn.h>

int puts(const char *s) {
    int (*pptr)(const char *);

    pptr = (int(*)())dlsym(RTLD_NEXT, "puts");

    write(2, "calling myputs: ", 16);
    return (*pptr)(s);
}
```

An alternative approach to wrapping is to invoke `ld-linux.so` directly from the program, and have it find the real `puts` routine. The call to `dlsym` above directly invokes `ld-linux.so`, asking it (as given by the first argument) to find the next definition of `puts` in the list of libraries. It returns the location of that routine, which is then called (`*pptr`).

## What's Going On ...

- **gcc/ld**
  - compiles code
  - does static linking
    - » searches list of libraries
    - » adds references to shared objects
- **runtime**
  - program invokes *ld-linux.so* to finish linking
    - » maps in shared objects
    - » does relocation and procedure linking as required
  - *dlsym* invokes *ld-linux.so* to do more linking
    - » RTLD\_NEXT says to use the next (second) occurrence of the symbol

# Delayed Wrapping

- **LD\_PRELOAD**
  - environment variable checked by *ld-linux.so*
  - specifies additional shared objects to search (first) when program is started

## Example

```
$ gcc -o tputs tputs.c
$ ./tputs
This is a boring message.
$ LD_PRELOAD=./libmyputs.so.1; export LD_PRELOAD
$ ./tputs
calling myputs: This is a boring message.
$
```

# Mmapping Libraries

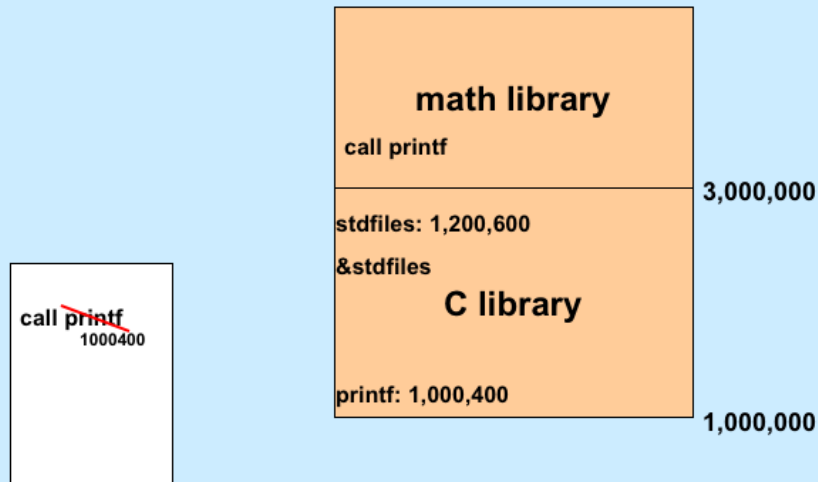

## Problem

- How is relocation handled?

## Pre-Relocation

Assuming we're using pre-relocation, the C library and the math library would be assumed to be in virtual memory at their pre-assigned locations. In the slide, these would be starting at locations 1,000,000 and 3,000,000, respectively. Let's suppose printf, which is in the C library, is at location 1,000,400. Thus calls to printf at static link time could be linked to that address. If the math library also contains calls to printf, these would be linked to that address as well. The C library might contain a global identifies, such as stdfiles. Its address would also be known.

**But ...**

Pre-relocation doesn't work if we have two libraries pre-assigned such that they overlap. If so, at least one of the two will have to be moved, necessitating relocation.

**But ...**

## Quiz 1

We need to relocate all references to Mary's library in my library. What option should we give to *mmap* when we map mylibrary into our address space?

- a) the MAP\_SHARED option
- b) the MAP\_PRIVATE option
- c) mmap can't be used in this situation

## Relocation Revisited

- **Modify shared code to effect relocation**
  - result is no longer shared!
- **Separate shared code from (unshared) addresses**
  - position-independent code (PIC)
  - code can be placed anywhere
  - addresses in separate private section
    - » pointed to by a register

## Mapping Shared Objects

The C library (and other libraries) can be mapped into different locations in different processes' address spaces.

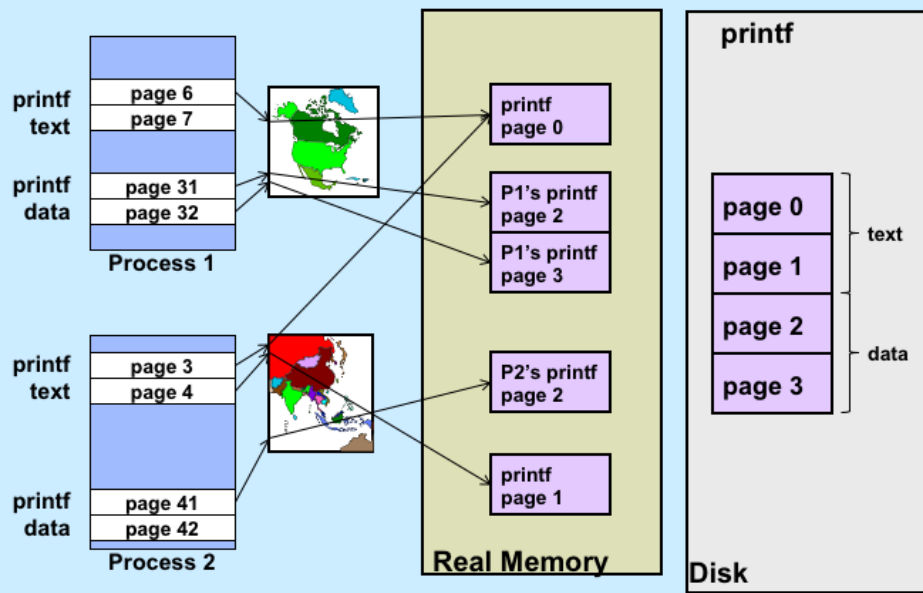

## Mapping printf into the Address Space

- **Printf's text**
  - read-only
  - can it be shared?
    - » yes: use MAP\_SHARED
- **Printf's data**
  - read-write
  - not shared with other processes
  - initial values come from file
  - can mmap be used?
    - » MAP\_SHARED wouldn't work
      - changes made to data by one process would be seen by others
    - » MAP\_PRIVATE does work!
      - mapped region is initialized from file
      - changes are private

For this slide, we assume relocation is dealt with through the use of position-independent code (PIC).

# Mapping printf

# Position-Independent Code

- **Processor-dependent; x86-64:**
  - **each dynamic executable and shared object has:**
    - » **procedure-linkage table**
      - shared, read-only executable code
      - essentially stubs for calling functions
    - » **global-offset table**
      - private, read-write data
      - relocated dynamically for each process
    - » **relocation table**
      - shared, read-only data
      - contains relocation info and symbol table

To provide position-independent code on x86-64, ELF requires three data structures for each dynamic executable (i.e., the program binary loaded by *exec*) and shared object: the *procedure-linkage table*, the *global-offset table*, and the *relocation table*. To simplify discussion, we refer to dynamic executables and shared objects as *modules*. The procedure linkage table contains the code that's actually called when control is to be transferred to an externally defined routine. It is shared by all processes using the associated executable or object, and makes use of data in the global-object table to link the caller to the called program. Each process has its own private copy of each global-object table. It contains the relocated addresses of all externally defined symbols. Finally, the relocation table contains much information about each module. What is used for linking is relocation information and the symbol table, as we explain in the next few slides.

How things work is similar for other architectures, but definitely not the same.

## Global-Offset Table: Data References

To establish position-independent references to global variables, the compiler produces, for each module, a *global-offset table*. Modules refer to global variables indirectly by looking up their addresses in the table, using PC-relative addressing. The item needed is at some fixed offset from the beginning of the table. When the module is loaded into memory, ld-linux.so is responsible for putting into it the actual addresses of all the needed global variables.

## Procedures in Shared Objects

- Lots of them
- Many are never used
- Fix up linkages on demand

## Before Calling Name1

```
.PLT0:
    pushq GOT+8(%rip)
    jmp   *GOT+16(%rip)
    nop;  nop
    nop;  nop
.PLT1:
    jmp   *name1@GOTPCREL(%rip)
.PLT1next
    pushq $name1RelOffset
    jmp   .PLT0
.PLT2:
    jmp   *name2@GOTPCREL(%rip)
.PLT2next
    pushq $name2RelOffset
    jmp   .PLT0
```

Procedure-Linkage Table

```
GOT:
    .quad _DYNAMIC
    .quad identification
    .quad ld-linux.so

name1:
    .quad .PLT1next
name2:
    .quad .PLT2next
```

Relocation info:

GOT\_offset(name1), symx(name1)

GOT\_offset(name2), symx(name2)

Relocation Table

Dealing with references to external procedures is considerably more complicated than dealing with references to external data. This slide shows the procedure linkage table, global offset table, and relocation information for a module that contains references to external procedures *name1* and *name2*. Let's follow a call to procedure *name1*. The general idea is before the first call to *name1*, the actual address of the *name1* procedure is not recorded in the global-offset table. Instead, the first call to *name1* actually invokes *ld-linux.so*, which is passed parameters indicating what is really wanted. It then finds *name1* and updates the global-offset table so that things are more direct on subsequent calls.

To make this happen, references from the module to *name1* are statically linked to entry *.PLT1* in the procedure-linkage table. This entry contains an unconditional jump (via PC-relative addressing) to the address contained in the *name1* offset of the global-offset table. Initially this address is of the instruction following the jump instruction, which contains code that pushes onto the stack the offset of the *name1* entry in the relocation table. The next instruction is an unconditional jump to the beginning of the procedure-linkage table, entry *.PLT0*. Here there's code that pushes onto the stack the second 32-bit word of the global-offset table, which contains a value identifying this module. The following instruction is an unconditional jump to the address in the third word of the global-offset table, which is conveniently the address of *ld-linux.so*. Thus control finally passes to *ld-linux.so*, which looks back on the stack and determines which module has called it and what that module really wants to call. It figures this out based on the module-identification word and the relocation table entry, which contains the offset of the *name1* entry in the global-offset table (which is what must be updated) and the index of *name1* in the symbol table (so it knows the name of what it must locate).

## After Calling Name1

```
.PLT0:
    pushq GOT+8(%rip)
    jmp   *GOT+16(%rip)
    nop;  nop
    nop;  nop
.PLT1:
    jmp   *name1@GOTPCREL(%rip)
.PLT1next
    pushq $name1RelOffset
    jmp   .PLT0
.PLT2:
    jmp   *name2@GOTPCREL(%rip)
.PLT2next
    pushq $name2RelOffset
    jmp   .PLT0
```

Procedure-Linkage Table

```
GOT:
    .quad _DYNAMIC
    .quad identification
    .quad ld-linux.so
```

```
name1:
    .quad name1
name2:
    .quad .PLT2next
```

Relocation info:

GOT\_offset(name1), symx(name1)

GOT\_offset(name2), symx(name2)

Relocation Table

Finally, `ld-linux.so` writes the actual address of the `name1` procedure into the `name1` entry of the global-offset table, and, after unwinding the stack a bit, passes control to `name1`. On subsequent calls by the module to `name1`, since the global-offset table now contains `name1`'s address, control goes to it more directly, without an invocation of `ld-linux.so`.
